Abstract

Despite the growing prevalence of Extended Reality (XR) headsets, their integration with mobile phones remains limited. Existing approaches primarily replicate the phone's interface in XR or use the phone solely as a 6DOF controller. This paper introduces a novel framework for seamless transitions among mirrored, magnified, and augmented views, dynamically adapts the interface with the content and state of mobile applications. To achieve this, we establish a design space through literature reviews and expert workshops, outline user journeys with common real-world applications, and develop a prototype system that automatically analyzes UI layouts to provide enhanced controls and spatial augmentation. We validate our prototype system with a user study to assess its adaptability to a broad spectrum of applications at runtime, reported its strengths and weaknesses, and suggest directions to advance the future adaption in Phone-XR integration.

Index Terms: Cross-Device Interaction, Phone-XR Intergration.

1 Introduction

The rapid evolution of Extended Reality (XR) headsets is ushering in a new era of immersive computing. While XR devices offer expansive virtual display spaces and immersive experiences, mobile phones remain indispensable due to their mature app ecosystems, intuitive input methods, and near-ubiquitous availability. Although XR-native applications could theoretically replace many mobile workflows, legacy user preferences and the convenience of phones highlight the potential of a hybrid approach [7, 48]. By integrating the strengths of both phone and XR, we can enable seamless, context-aware interactions that go beyond what either device alone can provide.

Recent research has explored integrating mobile phones with XR devices in various ways: using phones as 6DOF controllers [48, 3, 10, 24]; mirroring phone screens within XR environments [48, 13, 30, 3, 11, 50]; and extending phone interfaces with additional 2D panels [30] or 3D elements [48]. However, existing work primarily focuses on isolated modalities, such as using phones solely as controllers or enhancing display functionalities alone. In practice, interactions span multiple modalities that evolve across task stages with transitions. For instance, a user might start with phone-based input and later switch to augmented visuals for content review. Similar adaptions remain unexplored in existing works.

Furthermore, much of the prior work concentrates on mock-up applications with fixed interface, and typically designed for single-state scenarios. This approach limits generality and fails to provide solutions applicable to broader contexts beyond these prototype examples.

To address these gaps, we formulated the following research questions that guided our work:

1. What intermediate states and display enhancements can bridge the gap between fully replicating the phone interface in XR and fully migrating mobile workflows to XR, taking advantage of the unique capabilities of Phone-XR integration?
2. How can we design a framework that facilitates seamless transitions between interaction modalities across application states, accommodating the dynamic nature of real-world tasks?
3. How can we ensure that the framework is generalizable and adaptable, minimizing manual customization while maximizing usability and user experience?

Addressing these questions, we propose *Beyond the Phone*, a comprehensive framework that enables seamless multimodal interaction between mobile phones and XR devices. Our framework integrates the strengths of both devices and supports fluid transitions between various interaction modalities, catering to the dynamic nature of real-world applications.

A user journey, depicted in Figure 1, illustrates our framework above. The user initiates interaction by launching a shopping app mirrored within the XR environment (Figure 1a), allowing them to view the phone interface virtually while using the physical phone for input. Leveraging the unlimited display space of XR, the user transitions to a magnified view for enhanced readability (Figure 1b). Upon searching for a specific item, the user expands into an augmented view to examine the product in 3D (Figure 1c). Simultaneously, the phone interface in the user's hand transforms into a tailored control panel (Figure 1d), facilitating

*This project was conducted when the first author interned at Google. Corresponding authors: fyzhu@dgp.toronto.edu and me@duruofei.com

direct interaction with the augmented content. For instance, if the item offers color variants, the phone interface dynamically updates to present a color palette for selection. This dynamic modality switching, adapting the phone's role according to the application's stage, enables seamless transitions between phone-centric and HMD-centric interactions.

To achieve this framework, we conducted an expert workshop and a literature review to develop a design space accommodating both generalizability and dynamic transitions in phone-XR integration. Based on this design space, we built a prototype system capable of automatically analyzing app interfaces and enabling semi-automatic content adaptation aligned with application states.

To demonstrate our approach, we augmented six real-world applications and conducted a user study involving 12 experienced XR professionals to test the feasibility and applicability of our system. Our evaluation examined whether the proposed dynamic transition approach is universally optimal or if some applications benefit more from a single-view paradigm, providing insights into our framework and informing future research directions.

Beyond the Phone is therefore a combination of theory and practice in which we:

1. Based on an expert workshop and existing literature, depict a design space and user journeys for a diverse range of mobile applications, transitioning among different views that demonstrate both bi-directionality and adaptability.
2. Develop and implement a phone-in-XR prototype system that supports real-world applications, featuring a semi-automatic mechanism to switch between different views based on the content and the application's state. This approach highlights the generalizability of our system, allowing it to adapt to various applications without requiring extensive customization.
3. Validate the prototype system in a user study with 12 experienced XR professionals, in which we show the potential of our framework to improve phone-in-XR experience with real-world applications.

2 Related Work

Our work is inspired by prior research in cross-device interaction between phone and XR, as well as contextual UI understanding.

2.1 Integrating Smartphones with XR Environments

In recent years, considerable research has explored the integration of smartphones within XR contexts. One primary focus has been enabling users to view and interact with their phones while engaged in XR. Techniques such as screen mirroring [3] and passthrough windows [11] allow users to seamlessly attend to notifications or respond to text messages without leaving the immersion.

Integrating smartphones into XR presents significant challenges. Schneider et al. [36] evaluated the accuracy among different HMDs. Accurate interaction with a virtual representation of the phone requires precise touch calibration [49, 25], which depends on highly accurate reference frame alignment [23, 19, 28] and fingertip estimation [49, 25] using a comprehensive set of widely used techniques in this domain. Additionally, estimating hand dexterity is crucial for reliable interaction [44].

Leveraging smartphones as spatial controllers within XR has been another significant research direction. By incorporating 6DOF tracking and utilizing the phone's inherent haptic feedback, researchers have explored various interaction techniques. These include manipulating 3D widgets [27, 28, 25], text entry methods [13, 3], menu selections [48, 24], two-factor authentication [51], and data visualization [10]. Additionally, mid-air gestures using smartphones have been investigated as an input method for XR applications [6, 26].

Extending phone-centric content beyond the physical screen through XR has also been a focus. Techniques involving extended displays [30, 16] enable new interactions with 3D content [27, 38, 12] and bring static content to life [8]. Recent efforts have shifted towards creating cohesive design spaces for integrating smartphones within XR [48] and developing hybrid input that combine phone and controller interactions [46].

Overall, these projects have unveiled essential techniques, but often concentrates on isolated interaction modalities, focusing either on using smartphones as controllers or enhancing display functionalities independently. This compartmentalized approach overlooks the fluid nature of real-world interactions, where users frequently need to transition seamlessly between different input methods as tasks evolve. Moreover, prior studies often limit themselves to prototype applications designed for single-state scenarios, restricting their applicability to broader contexts.

In this work, we address these limitations by (1) highlighting the importance of seamless transitions between interaction modes driven by user intent and contextual adaptation, and (2) adopting an application-centric perspective to identify which functionalities are most relevant for diverse use cases.

2.2 Contextual UI Understanding in XR

To enable seamless transitions based on application content, it is essential to develop a contextual understanding of user interfaces within XR environments. Recognizing this need, Grubert et al. [14] envisioned a pervasive and context-aware XR, highlighting the unique potential of perceiving and interpreting the user's environment and context to support spatial content. They provided a foundational taxonomy at a time when the necessary technology was still emerging.

With advancements in the perception capabilities of XR devices, researchers have leveraged these improvements to dynamically adapt content—such as spatial user interfaces—based on environmental context [40, 5, 31, 35].For instance, Lindlbauer et al. [22] combined user awareness with spatial insights to determine both the placement and content of spatial widgets, while Pei et al. [33] investigated UI transitions across different entities. These efforts underscore the importance of contextual information in enhancing user interactions.

Building on these developments, subsequent research has further advanced UI understanding in XR. Li et al.'s *HoloDoc* [20], for example, explored a document-aware XR workspace that adapts to user activities. Similarly, Cheng et al.'s *SemanticAdapt* [9] proposed an optimization-based approach to generate XR layouts by leveraging virtual-physical semantic connections.

Insights from cross-device interaction research have also informed XR development, particularly in the digital augmentation of devices and objects using smartphones. Examples include the creation of extended display devices in spatial environment [37, 13], visualizing content from physical devices [10, 1], and utilizing the real environment as a canvas for interaction [2]. These approaches demonstrate how AR methods can enhance XR experiences, as seen in the transfer of accessibility features from AR on phones to HMDs to augment reading experiences [4].

Despite these advancements, determining how and what to augment based on real-world mobile applications and user interactions remains a complex challenge. In our work, we address this gap by performing content analysis of both the smartphone app UI and the user's behavior. By interpreting the application's state and the monitoring where the user's attention is directed, we dynamically decide on the most appropriate augmentation methods, managing different views and interaction states within the XR environment.

3 Beyond the Phone Framework

To explore and expand smartphone-XR integration, we conducted an expert workshop to inform a design space of display enhancements, phone interface, and Phone-XR interactions.

Application	Example	Pain Points on Phones	Display Enhancement	Tailored Interface
Web Browsing	Wikipedia	• Text readability • Screen size	• Expanded displays • Focused reading and summarization modes	• Touchpad (tap & multitouch) • Context dependent menus
Collaborative Work	Google Docs	• Inconsistent layouts • Editing challenges	• Multiple panels for drafting, editing, revising, etc.	• Keyboard (typing) • Touchscreen for markups
Photo Browsing	Google Photos	• Screen size	• Immersive gallery • Panoramic views	• Spatial (raycast) • Editing palette
Video Watching	YouTube	• Screen size • Environment distractions	• Immersive cinema view • Extended device screen	• Intuitive video scrubbing
Shopping	Amazon	• Lack of 3D and in-situ visualizations	• 3D in-home gallery view • Color/style palette	• Spatial (placement & manipulation)
Communication	FaceTime	• Limited embodiment • Transcription & augmentation	• 3D avatar views • Summarization views	• Keyboard (typing)
Navigation	Google Maps	• Lack of 3D visualization • Screen size	• 3D Overlays • Earth view	• Touchpad (tap & multitouch) • Context dependent menus
Social Media	Twitter	• Text readability • Screen size	• Embodied content • Immersive videos	• Keyboard (typing)

Figure 2: Results from the expert workshop. We have outlined the pain points of daily smartphone applications, proposed XR display enhancements, and potential phone-integrated input improvements.

3.1 Expert Workshop

In line with our goal to create a generalizable framework applicable to a broad range of real-world applications beyond mock-ups, we conducted an expert workshop to explore how daily smartphone applications can be utilized in phone-XR integration. The workshop involved nine professional researchers and software engineers from Google, each possessing extensive experience in developing immersive XR and mobile applications, thereby providing valuable insights for our analysis.

During the workshop, we first gave an overview of the existing literature on phone usage in XR (primarily the papers highlighted in Section 2), ensuring that everyone was familiar with the core aspects of this domain. After a thorough introductory discussion, we initiated a brainstorming session, engaging them in evaluating daily applications by considering the following aspects:

1. Identifying the pain points of the application when accessed solely through a physical phone.
2. Exploring potential display enhancements that could be applied to this application within an XR environment.
3. Considering alternative interfaces that could transition from the phone to enhance input when the application is expanded into an XR format.

The workshop results, summarized in Figure 2, revealed a widespread need for enhanced display capabilities, such as larger virtual screens, multiple views to present diverse content, and the ability to display 3D content at a life-size scale. Participants also emphasized that while the tangible nature of smartphones remains valuable for input, these inputs must adapt dynamically to the application's state and context, requiring seamless alignment with the content presented.

In discussing intermediate states between fully replicating the phone interface and pure XR applications, participants proposed moving beyond prior works focused on tethered phone interfaces [48, 3, 24, 30]. They suggested incorporating floating, magnified views and augmenting these views with multiple enhanced setups to address diverse content and interaction requirements. This approach allows users to retain access to the original phone interface while benefiting from XR's unique capabilities. Additionally, they recommended tailoring the phone interface dynamically, adapting it to function as either a controller or content display, depending on the application's state and specific needs.

These findings underscore the importance of dynamically alternating between mirrored and tailored interfaces, depending on the task's needs and application state. They provide a strong foundation for designing a system that bridges smartphone and XR capabilities, aligning closely with our research questions. Specifically, they inform the design of intermediate states (RQ1), seamless transitions between modalities (RQ2), and adaptable solutions that minimize manual effort (RQ3).

3.2 Design Space

To effectively guide the design process and align it with the points proposed above, we introduce a design space depicted in Figure 3. This design space outlines different states for both display enhancements and phone interfaces, allowing transitions between them. It includes considerations for display enhancements in the XR setting and context-responsive adjustments to the phone interface. Moreover, our proposed interactions integrate touch inputs with spatial dynamics, encompassing the movement and spatial relationship between the phone and the XR system.

As previously highlighted in the workshop, existing research has focused on interfaces that are solely attached to the physical phone, typically applying only a static modality—either as a controller or as extended views—without transitioning between modalities across different application states.

To bridge the gap between these limitations and the need for dynamic modality transitions, we propose a solution that encompasses different modality views, including mirrored, magnified, and augmented views, utilizing the *Magnified View* as an **intermediary state for transition**. Users can simultaneously utilize both the mirrored and magnified views or employ the magnified view as a preliminary step to initiate augmented views when needed. When the augmented views are presented, the Magnified View retains the original application content, while the phone interface transitions to a tailored interface, incorporating appropriate input widgets that correlate with the augmented content currently in use, such as buttons. The capability to dynamically alternate between display enhancements fosters a cohesive transition experience, effectively unifying what were once isolated components.

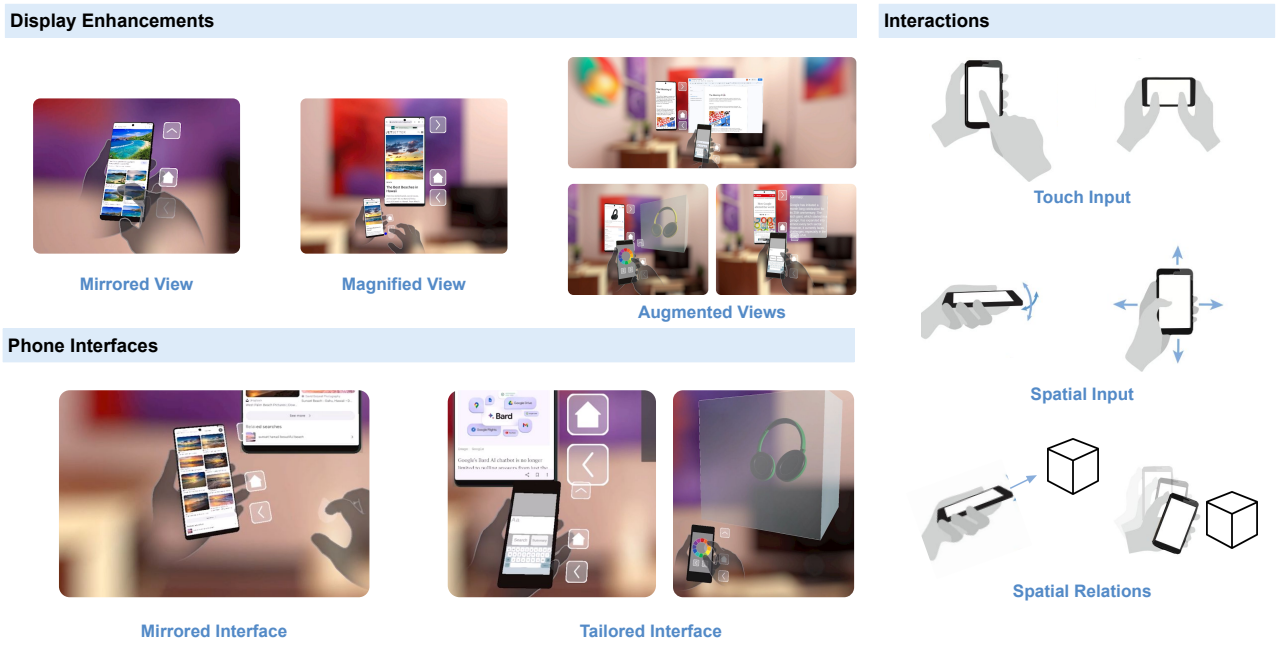

Figure 3: The *Beyond the Phone* design space we explore with, including: (1) Display Enhancement methods of varying immersion, (2) Phone Interfaces that applied based on different context, and (3) Interactions.

We emphasize that our approach does not entail the creation of each component in isolation. Similar to the approach applied by previous works [48, 10], our work primarily involves the synthesis and integration of existing research knowledge to effectively construct a design space tailored to specific needs. In the following section, we provide a detailed explanation of how each element functions within this design space and discuss related works that exhibit similar concepts.

3.2.1 Display Enhancements Aligned with App States

We implement three types of display enhancements, each representing a distinct state closely aligned with application content. These enhancements enable **seamless transitions** between states, dynamically adapting to the application's context. We detail each enhancement below.

Mirrored View [3, 18]: This enhancement creates an exact digital replica of the smartphone's interface within the XR environment, aligned with the physical phone's spatial orientation. In application states where direct interaction with the phone's native interface is most appropriate, users can interact with their phone just as they would in the real world with this setup.

Magnified View [13, 30, 25, 50]: When the application requires enhanced readability or a larger display area, the system transitions to the magnified view. This enhancement projects the smartphone's interface onto a larger virtual canvas within the XR environment, overcoming the limitations of the phone's physical screen size. Users can interact with both the physical touchscreen via the mirrored view and the enlarged content of the magnified view using mid-air gestures. The magnified view also acts as an intermediary state, allowing seamless transitions between direct touch and spatial interactions, aligned with the application's needs.

Augmented View [48, 13, 25]: For application states that benefit from additional content or 3D representations, the system enhances the display by overlaying augmented content onto the XR environment. This may include alternate user interfaces, realistic 3D representations for object previews (e.g., for shopping), or supplementary 2D content (e.g., news summaries). The physical phone interface adapts to become a customized controller, incorporating input widgets that correlate with the augmented content relevant to the current application state.

3.2.2 Seamless Transitions Between Enhancements

Our approach allows for dynamic transitions between these display enhancements based on the application's state and user actions. The magnified view serves as a bridge between the mirrored and augmented views. Users can activate the magnified view from the mirrored view when they need a larger display, and from there, they can initiate the augmented view to access enhanced content. Throughout these transitions, the original application content remains accessible, and the input modalities adapt to provide the most intuitive interaction methods.

By aligning the display enhancements with application states and enabling smooth transitions between them, our system fosters a cohesive and adaptable user experience. This design ensures that users can naturally progress through different phases of interaction without disruption, effectively unifying what were once isolated, which also guaranteed the bi-directionality during the transition [48].

3.2.3 Phone Interfaces

The *phone interface* in our framework refers to the interface that is superimposed onto the physical device. We utilize two distinct modalities:

The **Mirrored Interface** [3, 18, 11, 50] refers to the exact replication of the phone's interface within the virtual environment. This modality serves a dual purpose, offering both a **Mirrored View** and control over content within the **Magnified View**.

The **Tailored Interface** refers to the alternative interface that transform the phone into a controller to facilitate enhanced interaction when the **Augmented View** is activated. This typically involves using the smartphone as a tactile controller [24, 28, 25, 41, 13, 48], equipped with widgets that are contextually relevant to the current content displayed.

3.2.4 Phone Interactions

To fully leverage the potential of phone interactions in XR, which can enhance context understanding and improve usability, we

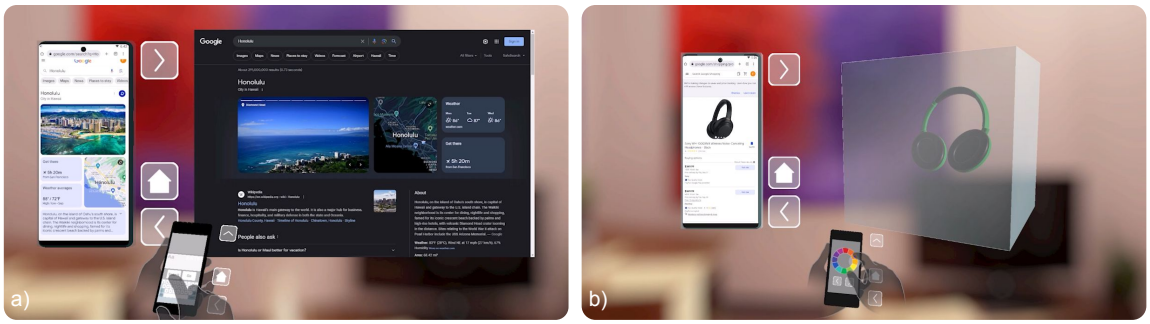

Figure 4: Example of how different applications are augmented uniquely in *Beyond the Phone*: a) a desktop webpage view and text-input view to support web-search application; b) a 3D product preview and customizable color palette for shopping application.

categorize phone interactions into three distinct levels:

Touch Input: The phone acts as a touch input device, accommodating familiar interactions such as tapping and text input, addressing the precise input needs that often lack with XR devices.

Spatial Input: The phone's spatial features can also be leveraged as an input. Users can utilize its 3DOF orientation or its full spatial movement capabilities in 6DOF to provide additional input modalities.

Spatial Relations: Here, the phone's spatial relationship with virtual or augmented elements forms the basis of interaction. Unlike the previous two levels, this approach focuses on using the phone's relative position to manipulate virtual objects within the XR environment.

3.3 Application-Adapted Views

Our workshop revealed that application-centric information can be effectively leveraged as a context source [14] for augmented smartphone interactions in XR. This perspective differs from much of the prior research on Phone + XR, which has primarily adopted a device-centric approach [48].

Drawing inspiration from methodologies presented by Lindlbauer et al. [22, 9, 42], we propose a Smartphone UI Understanding approach that applies augmented content across different applications. Our approach utilizes the content and potential controls within on-phone applications to enhance interactions in XR environments. For example, Figure 4 demonstrates two scenarios: in a web-search application, the augmented view is transformed into a desktop-like interface for improved visualization, with the phone's tailored interface becoming a virtual keyboard for easier text entry. In a shopping application, the augmented view displays 3D product previews, while the phone interface adapts by incorporating a color palette, allowing for style selection.

The expert workshop results serve as a valuable reference for implementing these augmented interactions, supporting their generality and adaptability within our frameworks. Further technical details on how to implement this approach will be discussed in the following section.

4 Implementation

To gain a hands-on understanding of the design decisions in our framework and to assess it with actual users, we developed an interactive prototype integrated with UI understanding, with the system architecture shown in Figure 5.

Previous studies have developed various methods for phone tracking and user interface mirroring in virtual reality environments. Most research utilizes an external tracking system to track the physical phone [48, 24, 3]. For the interface attached to the physical phone, existing works either employ direct video streaming [3, 18] or construct a simulated interface in their demonstration applications, which does not accurately mirror the actual content visible on the phone [48, 24]. These methods often do not separately process input and output related to the smartphone interface during deployment.

For our system, *Beyond the Phone*, we aim to enable the phone to support multiple views, particularly as the device transitions between phone and controller modalities. This requires a separate processing approach where the phone's interface is treated as output, and input is fused with both spatial input and touch, independent of the phone's touch surface. This builds upon the foundational work of SAPIENS-in-XR [32] and XRStudio [29], which explore XR system architectures and interaction frameworks, which leading us into our system design that achieves the following:

1. The interface that represents the phone content is a real mirror of the physical phone, rather than a mock-up. This applies to both the **Mirrored View** and **Magnified View**.
2. Input from the physical screen does not directly influence the original phone interface shown in XR. Instead, the XR system controls the input, combining touch and spatial gestures as a unified input source.
3. The updates of the **Mirrored View** and **Magnified View** are independent of physical touch from the phone, instead controlled by combined inputs from touch, spatial input, and commands/events from the XR system.
4. The **Augmented View** is updated with UI analysis results from the context of the current phone application, rather than preset mock-ups.

Figure 5 shows how we achieve these requirements. In general, the phone interface and touch events are separately processed via our protocol. The UI analysis and input system are regenerated through our system. Drawing inspiration from prior research such as Bai et al. [3], we leveraged a customized WebRTC approach to relay the screen texture to our backend. The physical phone also supplies 6DoF tracking information and transmits touch events to the server.

In the following sections, we will introduce two techniques from our exploration. The Hybrid Input technique is designed to eliminate the influence of tracking errors, while the UI analysis process provides a general solution for content understanding.

4.1 Hybrid Input

The Hybrid Input technique, based on the work by Zhu et al. [49], is established to eliminate the inevitable tracking errors between hands and phones. [36] In terms of input for a multi-device system, we can identify three unique "Pointer Events" within our system:

- **Virtual Touch**: This event is detected when the virtual fingertip interacts with the virtual phone.
- **Physical Touch**: This event is triggered when the user's real finger comes into contact with the physical phone.
- **Spatial Input**: These are spatial gestures, such as raycasting + pinch to interact with the Magnified Screen.

If tracking was perfectly accurate, both the Virtual Touch and Physical Touch events would coincide without any disparity. Yet,

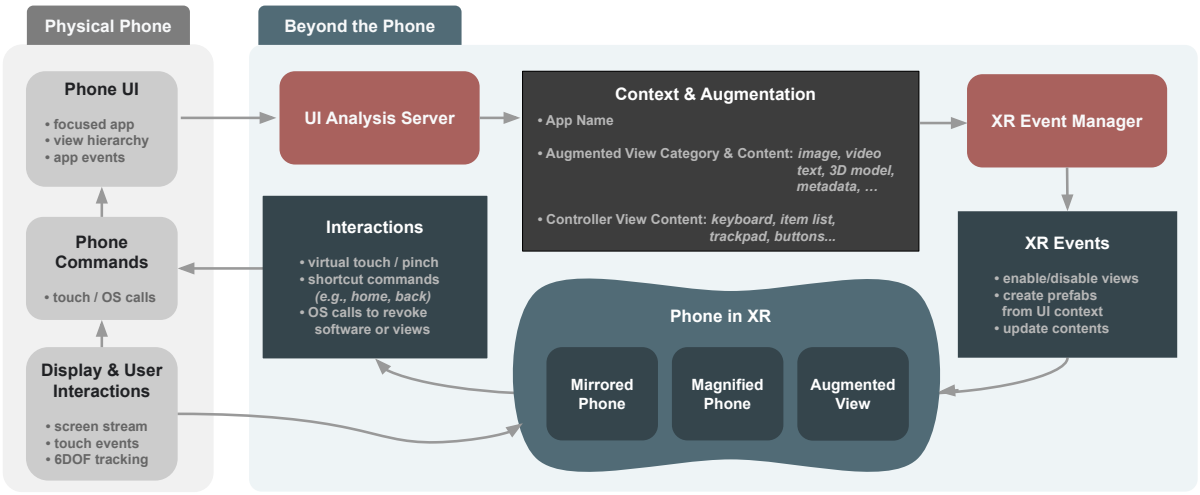

Figure 5: *Beyond the Phone* prototype architecture: On the left is the physical phone, with input and output conceptually divided for clarity. The right side maps out the process, including a UI Analysis Server, a XR event manager, and proper data flow towards different phone views in XR. The XR input will also be injected into the physical phone, either as pointer events or shortcut commands.

achieving accurate tracking of both the phone and hands in XR is rarely the case in real scenarios. Such deviations can lead to mismatches between these two events, in which the touch visually perceived by the user is different to what the touchscreen registered, akin to the "fat-finger problem" in touchscreen input.

To overcome this problem, and drawing from the insights of Zhu et al. [49], we implement a **Hybrid Touch** strategy. This approach utilizes the Virtual Touch to determine the 2D touch point on the virtual phone, while the Physical Touch on the real screen is used to confirm the touch upon physical contact with the surface.

In order to capture the spatial position and touch events from the phone, we designed a companion application that captures and transmits all touchscreen interactions to the XR + phone experience. This ensures precise implementation of hybrid touch and spatial input, while also enabling the phone to function as a custom spatial controller.

For quick access functions, such as 'home' and 'back', we embedded several UI widgets surrounding the virtual phone model (See Figure 1 and Figure 5). These widgets are tied to specific `adb shell` commands, pragmatically triggering the desired inputs. This design not only facilitates intuitive operation in the XR environment but also minimizes false inputs typically associated with global gesture controls, as these widgets are spatially distinct and float in the virtual space.

4.2 Screen Streaming

Unlike previous works that directly synchronize the phone screen with the system [3, 24], our approach, which integrates Hybrid Touch, Spatial Input, and System Shortcuts, updates the Android view only after processing these inputs collectively. This is achieved through system-level input injection into the Android emulator, involving necessary adjustments to events and visual presentations. Once updated, this view is then sent to the UI Analysis Server for further processing.

For the Mirrored Views, we decided to use streaming textures and mapping on the phone interface instead of relying on direct video pass-through. We made this choice because current video pass-through methods often result in issues such as distortion, improper exposure, and low resolution—all of which degrade the user experience.

Beyond transmitting the screen image, our system leverages application states for content augmentation. Therefore, we also send metadata, such as the view hierarchy, through the same channel. The details of this process will be further discussed in the section §4.3.

4.3 UI understanding

For our prototype, it is crucial to identify the currently focused application and content. This foundation enables us to discern what immersive content should be projected spatially and how to optimize the phone's functionality as a controller.

As indicated by prior research, the optimal method involves UI analysis utilizing the *UIAutomation* tools that Android natively offers. Drawing on the procedures adopted by previous work [43, 17, 47], we implemented a streamlined UI Analysis Server to obtain context-sensitive metadata. This server acquires screenshot, the view hierarchy in XML (see an example in the Appendix), and event log from the phone. Subsequently deducing metadata such as the **Application Name, Focused Content, and Main Activity Bounding Box.** We then attempt to match those data with the outcomes from our design workshop, which contains a set of different widgets for tailored views and content automation that could be applied for augmented views. As for our current design, the potential content that could be augmented includes 3D objects preview for certain types of objects, gallery views for multiple photos, digest of article, video player, online text editor and web browser based content. The potential tailored views includes widgets like keyboard, video player controller, color palette, list selection elements, and ray based pointer. Those widgets could be organized with multiple objects in the same view. For unlisted applications, the bounding box of the Focused Content is returned for direct content expansion (see Figure 5).

After successful matching, the server sends the relevant details back to the XR application, including the content meant for augmentation and the anticipated category at the time of the request. The XR application uses this information to update the XR assets appropriately while also toggling enable/disable states based on user inputs.

4.4 Setup and Apparatus

Our prototype uses a Pixel 6 Pro phone paired with a Meta Quest Pro headset. The software was developed using Unity 2021.3.4f. The mobile companion app was directly built in Android and relays touch events and tracking details to the XR application through UDP. UI automation procedures were initiated through `adb shell` commands from the server end. Oculus SDK supplied the hand

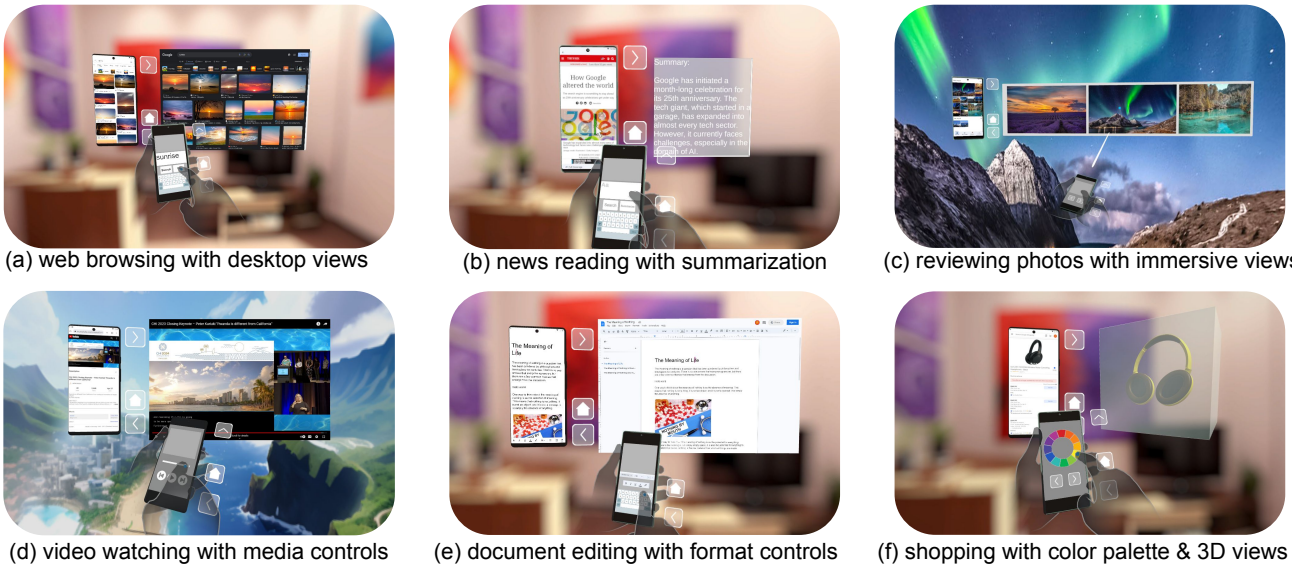

Figure 6: Example applications augmented with *Beyond the Phone* for the evaluation: (a) browsing image-extensive webpages with desktop views, (b) using text-heavy apps with summarizing views, (c) exploring photos with gallery and immersive views, (d) using YouTube with media controls, (e) editing online documents with phone keyboards and format controls, and (f) online shopping with color palette in phone and 3D augmentation spatially.

tracking information. To track the phone's position and orientation in the XR environment, the companion app runs ARCore's 6DOF tracker in the background. Meanwhile, the hand tracker is used to calibrate the phone's coordinate alignment with the XR space when held in a specified manner.

Specifically, since the system encompasses multiple communication channels with varying layers of information exchange between the XR system and the smartphone, necessitating attention to different levels of latency. To minimize transition delays for data such as the view hierarchy and screenshots, which are critical for real-time UI analysis, we used an Android Emulator on a workstation to provide the phone interface. As mentioned above, the physical phone supplies tracking and touching data to the server. The server then forwards these inputs as well as XR event to the Android Emulator, which updates the displayed interface. This setup allows us to either faithfully mirror the interface on the physical phone or substitute an alternative interface on the phone, all while ensuring the system accurately reflects and interacts with the phone content in real time.

During testing, the mirroring interface and synchronized tracking took approximately 60ms for a complete cycle, while the UI automation procedures via ADB required around 2-3 seconds for server-side analysis. Therefore, in our final development, we set tracking and screen mirroring to update continuously for smooth interactions. In contrast, UI analysis via UI automation is triggered as needed, as illustrated in Figure 5.

4.5 Applications

Following the insights gained from our workshop, we selected six applications for the evaluation (see Figure 6). All the phone applications are directly downloaded from Google App Store without any modification.

The applications include a 3D object viewer that enhances the shopping experience, a spatial gallery extension compatible with system photo app, a concise summary feature support news reading , a document editing tool, a video player with on-phone controls, and a spatial web browser. Full demonstration videos for each application can be found in the supplementary materials.[1]

[1]They are also available on YouTube at this playlist.

The selection was driven by the diverse configurations and the range of content each application offers, ensuring broad coverage of various use cases. In terms of content preview, these applications encompass text-based information, 2D media, and 3D object displays. From an interaction standpoint, they span purely passive viewing, searching, editing object attributes, document editing, and interactive video playback. Taken together, this diverse set of applications provides a comprehensive testbed for our user study, allowing us to evaluate our frameworks across multiple interaction contexts and to validate its versatility.

5 User Study

To validate our proposed system and make an assessment of our frameworks and their effectiveness in real-world applications, we conducted a user study to gather user feedback on these features.

5.1 Study Setup

The study aimed to examine the performance of our frameworks across multiple deployed applications. Specifically, we sought feedback on: (1) How the intermediate states introduced (e.g., Magnified Views and Augmented Views) were perceived compared to a straightforward phone replica (Mirrored Views). (2) Whether our proposed transition mechanisms (including phone mirroring, spatial magnification, multi-view setups, and augmented configurations) provided a coherent user experience across different views.

We recruited 12 participants (3 female, aged M=33.7, SD=9.9), all of whom were professional UI designers, researchers, or software engineers at Google. Each participant had substantial experience in creating immersive experiences, ensuring a knowledgeable user base for our evaluation. The study was approved by the ethics board of Google Research.

Each session lasted 45–60 minutes and consisted of four stages: (1) a tutorial; (2) an exploration of *Beyond the Phone* with the six applications mentioned above; (3) a questionnaire that captured preferences for different views and perceived coherence and consistency for each application; and (4) a follow-up interview.

Rationale for Expert Participants. We chose expert users to minimize the "novelty effect" often observed in cross-device interactions among novices. Non-experts tend to favor new modalities simply because they are unfamiliar, which can bias

objective evaluation. In contrast, experts—through broader exposure and design experience—are less susceptible to novelty bias and thus offer more critical, focused feedback. Furthermore, interviews with expert participants are more likely to yield detailed discoveries relevant to both design and implementation, making their expertise crucial for a robust evaluation.

Tutorial and Exploration. Before starting the study, participants first signed a consent form and answered a demographic questionnaire. Each participant was then introduced to our system through a series of introductory slides and tutorial videos. This familiarization process included instructions on starting the application, calibrating the tracked phone, and launching features like the Magnified Phone View and Augmented View. Subsequently, participants engaged with the six applications depicted in Figure 6. Participants began with a standardized application journey. After successfully completing the controlled tasks, they were allowed to freely explore content that suited their needs, such as different YouTube videos or news articles. The order of applications was randomized for each participant to ensure unbiased feedback. This exploration allowed participants to interact with diverse functionalities, including document editing, web browsing, online shopping, news summarizing, video watching, and photo browsing.

Questionnaire and Interviews. Once completing the exploration phase, participants undertook a review of each application scenario. This was achieved through a questionnaire, participants were asked to rank their personal preferences regarding phone representation for each application. *(For the application above, please rank your personal preference of phone representation)*

Meanwhile, since all the applications combined the use of three views in transition, we also asked the participants about their perceived coherence level of the whole transition process in this immersive environment using a 5-point Likert scale. *("How would you rate the coherence level of the transition process among the three views (Mirrored, Magnified, and Augmented) in this application?")*

After completing the questionnaire with individual applications, participants were then asked about their comment the overall of the system. We then conducted interviews to gather participants' rationale and suggestions for improving the prototype, with a primary focus on their feedback and on expanding the comments they had provided in the questionnaire.

5.2 Results

All participants found our system intuitive and easy to use. For the results of preferences, participants ranked their preferences for Screen Mirror, Magnified, or Augmented Views for each application. A scale of (0, 1, 2) was used, where 0 represents the least preferred view and 2 represents the most preferred. The values presented in Figure 7a represent the average preference scores based on participants' rankings.

The results reveal two key insights:

1. Participants consistently favored views that went beyond simple mirroring, with Mirrored Views receiving the lowest preference scores across all applications.
2. Preferences for Augmented and Magnified Views varied depending on the application. Applications featuring media such as 3D shopping previews, videos, and photos saw a clear preference for Augmented Views. In contrast, for applications designed primarily for 2D content, the preferences for Magnified and Augmented Views were more balanced, with minimal differences in preference.

We conducted a Friedman chi-square test to analyze the differences in preference scores across the three views (Mirrored, Magnified, Augmented) for each application. Significant differences were observed for all applications. For example, Browser ($\chi^2 = 15.17, p < .01$) and Shopping ($\chi^2 = 16.55, p < .01$) both showed highly significant results. Pairwise Wilcoxon tests with Bonferroni correction revealed significant differences between Mirrored views and the other two views (Magnified and Augmented) across most applications.

Further analysis focused on the perceived coherence for each application, assessed on a 5-point Likert scale (1 = strongly disagree, 5 = strongly agree). As shown in Figure 7b, the results are visualized through violin plots to display the distribution of scores.

Most applications received high scores, suggesting that participants generally found the combination of views and transition process to be coherent. Similar to what we found in the ranking results, for for applications designed primarily for 2D content, the score distribution varied across the results. Participants indicated that simpler displays, such as extended or magnified views, were more appropriate for this context, as confirmed during follow-up interviews.

5.3 Interview Findings

Reported Strengths of Our System Interview feedback was overwhelmingly positive, with many participants praising the system's improved usability, legibility, and immersive experience. They frequently highlighted enhanced reading ease and overall engagement. For instance, participants stated *"The ability to read small text is greatly improved with the larger views."* (P6), *"I feel more immersed when I browse the web."* (P9), and *"I can view my object in a more immersive way, compared to being constrained in a small display device."* (P8)

Others noted the expanded interaction capabilities: *"I like the idea of using the phone as a pointer."* (P11), *"I appreciate the concept of keyboard typing on the phone."* (P9), and *"I think this would make a lot of sense for YouTube, because the phone can operate like a TV controller for YouTube (play, pause, skip forward and backwards)."* (P6)

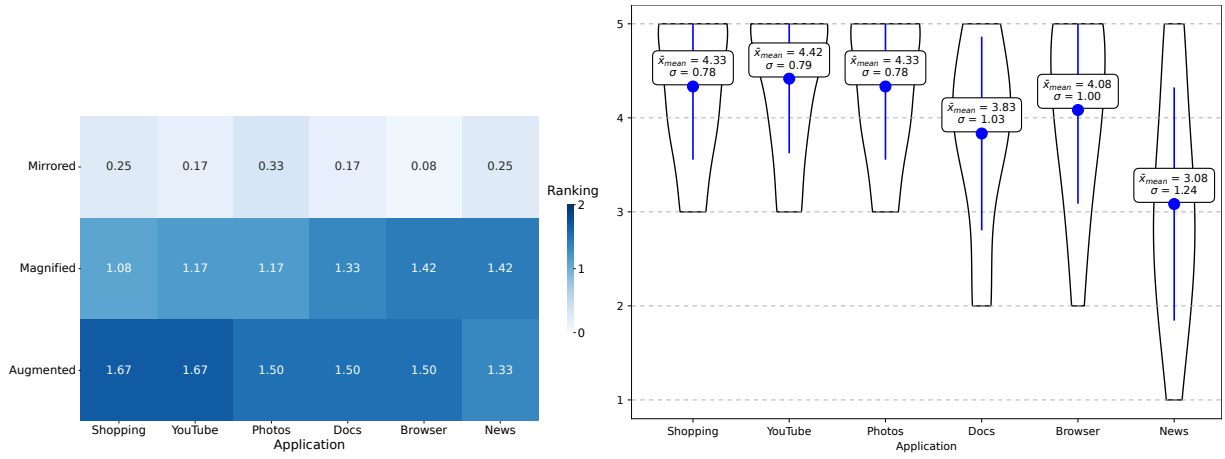
Furthermore, participants widely praised the augmented view corresponding to specific applications. For instance, participants stated *"Viewing 3D headphones is really impressive."* (P10), *"The text summary saved my time."* (P2), *"viewing photos is easier for the user"* (P1), and *"you can control various aspects of the 3D object (color, sizes) very easily."* (P7)

Application-Specific Preferences: In our ranking and coherence reports, we observed differing preferences for various views across different applications, which was also hinted at in the interviews. One potential reason for these differences is the overwhelming amount of information presented in Augmented View setups when reading is required. As noted by participants: *"I keep looking up and down, which may not be ideal."* (P5) and *"Switching views from the magnified phone to the smaller one felt disorienting."* (P8) This suggests a **desire for more explicit view options**. Some participants also provided application-specific feedback: *"If I'm watching YouTube Shorts, the large phone would be preferred. Traditional videos would need the extended view, as they are in landscape format."* (P3), and *"For Google Docs, I always prefer reading in the Augmented Views."* (P6)

Additionally, participants expressed a desire for configurable, personal choices in view settings. For example, P11 noted: *"For the news scenario, the physical phone seems redundant, but it might be indispensable for a shopping preview."* This prospect warrants further exploration in future studies.

6 Discussion and Future Works

With *Beyond the Phone*, our goal was to create an enhanced Phone-XR experience that goes beyond basic screen mirroring or a one-size-fits-all controller. To achieve this, we designed dynamic modality switching and adaptable interactions across real-world applications. We are pleased to report that our deployment results demonstrated the system's effectiveness. Feedback from the user study was overwhelmingly positive, with participants adeptly



(a) Preference rankings of Mirrored, Magnified, and Augmented Views across each application.

(b) Perceived level of coherence and consistency across different views for each application.

Figure 7: Results from the quantitative studies.

navigating through various views and finding the transitions not only useful but also well-suited for real-time interactions. This outcome aligns with our initial vision of elevating the role of the phone from a mere controller or display mirror to an integral component of the XR experience.

We want to clarify that we are not asserting Phone+XR surpasses fully ported XR applications (e.g., a dedicated XR version of YouTube). Rather, we build on prior research indicating that phone–XR integration offers unique advantages worthy of further exploration. Compared to existing projects [48, 30], our work introduces two key innovations: the use of real-world applications instead of mock-ups, and a seamless transition mechanism between multiple views that aligns with both application states and content. Our evaluations revealed that users had distinct preferences for different views based on the application, offering valuable insights for future development of phone applications within XR.

Our system, which focuses on integrating smartphones into XR, fits within a broader multi-device landscape that includes desktops, tablets, and wearables such as smartwatches. The strategies we developed—particularly for transitioning between views and augmenting content within the Phone-XR interface—could be adapted for these devices, opening new avenues for future research to extend our approach to a wider range of platforms.

Additionally, our method for implementing augmented views on phone interfaces could serve as a foundation for enhancing existing 2D applications within XR environments. By analyzing existing UIs and applying augmented content across multiple views, our framework provides a roadmap for seamlessly transitioning these applications into XR settings.

In our preliminary prototype, we implemented a universal solution with one augmented view per application. Future iterations could feature multiple views per application, different transition workflow, customized to better understand the application context. There is also potential for user-configurable view settings based on personal preferences. This variability presents an exciting challenge: determining the optimal view setup for each application, which we identify as a key area for future exploration.

As video pass-through techniques become more advanced, the issue discussed in Section 4.2 may become less relevant. In such a scenario, a video see-through phone could serve as a more suitable replacement for our Mirrored view. Nevertheless, we believe our framework would remain viable under these conditions—particularly in demonstrating how augmentation can enrich the general user experience. Further evaluation could be conducted to explore this use case.

As all participants in our study were experts from our institution, the findings may not necessarily generalize to novices, students, or other professionals. Future work should therefore involve expanding the participant pool, including non-experts and everyday users, to more thoroughly assess the frameworks.

Another limitation of our proof-of-concept system is that *Beyond the Phone* 's UI Analysis Server is currently tailored to a specific set of applications, and its 3D asset generation is limited to predefined references. However, we are optimistic about future improvements, as emerging technologies like text-to-3D conversion [34, 21, 45, 15] have the potential to significantly enhance the XR experience by enabling the creation of more dynamic 3D content.

We also anticipate that advancements in AI, particularly in scene understanding and segmentation [39], will further enrich UI context understanding in XR environments. Future work could leverage OS-level metadata to enable seamless recognition and augmentation of phone apps in immersive settings.

7 Conclusion

In this paper, we introduced *Beyond the Phone*, a novel framework that enables seamless integration of smartphones into XR environments through dynamic multi-view transitions for real-world applications. Unlike traditional methods that limit smartphones to screen mirroring or basic controller functionality, *Beyond the Phone* enhances the XR experience by enabling fluid transitions between mirrored, magnified, and augmented views, dynamically adapting to the content and the current state of the application. By leveraging user-centered design and real-time adaptability, our system creates a more immersive and interactive Phone-XR experience.

Beyond the Phone distinguishes itself by offering an adaptable, multi-view interaction model that breaks away from the conventional binary view of smartphones as either simple controllers or mirrored displays in XR. This flexibility opens up new possibilities for richer, more interactive mobile experiences in XR environments, moving beyond the limitations of existing methods.

While *Beyond the Phone* represents a meaningful step forward in integrating smartphones within XR environments, we recognize it as an early stage in addressing this complex challenge. We are excited about future developments that will build on this foundation, contributing to continued innovation in this exciting domain.
